General information

Avoid multiple print statements

It is always a good idea to avoid excessive use of `print` statements, in order not to clutter your source code. As such, it becomes much easier to track what exactly will be printed and how the output is formatted.

Say, for example, that you have the following source code

```
>>> x = 3
>>> if x < 5:
...     print('less than 5')
... else:
...     print('more than 5')
...
'less than 5'
```

It is better to rewrite this source code as

```
>>> x = 3
>>> if x < 5:
...     result = 'less'
... else:
...     result = 'more'
...
>>> print('{} than 5'.format(result))
'less than 5'
```

Possible errors

Python issues a runtime error if you try to fetch the value of an object referenced by a variable that has not been defined earlier in your source code (not object has been assigned to this variable). This happens for example in the following code fragment

```
>>> x = 4
>>> if x < 3:
...     var = 'ok'
...
>>> print(var)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
NameError: name 'var' is not defined
```

where the `print` statement issues a runtime error that mentions the fact that the variable `var` could not be found in the namespace. If you carefully examine the code fragment, you'll see that the variable `var` is not assigned a value in case the value of `x` is larger than 3 (which is the case in this example).

Finding mates

General information

Testing if the value of a variable belongs to a fixed set of options

The following conditional statements have a logical error in checking whether or not it is weekend or a working day on a given weekday. Actually, the condition will always be `True`, suggesting that it is forever weekend.

```
>>> weekday = 'sunday'
>>> 'weekend' if (weekday == 'saturday' or 'sunday') else 'working day'
'weekend'

>>> weekday = 'monday'
>>> 'weekend' if (weekday == 'saturday' or 'sunday') else 'working day'
'weekend'
```

The reason things go wrong is that the condition is composed out of two smaller conditions, being `weekday == 'saturday'` and `'sunday'`. The second condition is always true, since any string is `True` except for the empty string which is `False`. The correct way of formulating the composed condition is

```
>>> weekday = 'sunday'
>>> 'weekend' if (weekday == 'saturday' or weekday == 'sunday') else 'working day'
'weekend'

>>> weekday = 'monday'
>>> 'weekend' if (weekday == 'saturday' or weekday == 'sunday') else 'working day'
'working day'
```

Note the repetition of the variable name in the condition.

Remarks

In Python the syntax of an assignment statement uses a single equal sign, where an equality test (check whether two objects have the same value) uses two successive equal signs. To check if the value of the variable `x` equals the integer 2, you write

```
>>> if x == 2:    # correct
...     pass
```

and not

```
>>> if x = 2:    # wrong
File "<myscript.py>", line 1
    if x = 2:
        ^
SyntaxError: invalid syntax
```

General information

Conditional expressions

You can use a conditional statement, if you want the value that must be assigned to a variable to depend on a certain condition. Say, for example, that you work with the variable `x` that refers to the length of a person (in centimeters), and that you want to assign the value `'large'` to the variable `length` if $x > 185$, and the value `'small'` otherwise. Using a conditional statement, this can be done in the following way.

```
>>> x = 100
>>> if x > 185:
...     length = 'large'
... else:
...     length = 'small'
...
>>> length
'large'

>>> x = 190
>>> if x > 185:
...     length = 'large'
... else:
...     length = 'small'
...
>>> length
'large'
```

The same result can be obtained using an `if-else`-expression (also called a *conditional expression*). In contrast with a conditional statement, this is an expression (that evaluates into a value) and not a statement. As a result, you may use conditional expressions in the right-hand side of an assignment statement. Using conditional expressions, the above interactive session can be written much shorter.

```
>>> x = 100
>>> length = 'large' if x > 185 else 'small'
>>> length
'small'

>>> x = 190
>>> length = 'large' if x > 185 else 'small'
>>> length
'large'
```

General information

Check if a number is between two limits

In Python you can check if the value (of a variable) is within a certain interval by using a composite Boolean expression. For example, if you want to check whether or not the number `x` is in the interval $]a, b[$, you can

use the following Boolean expression

```
>>> a < x and x < b
```

In mathematics, this condition would be written as $a < x < b$, and Python can use the same kind of shorthand notation.

```
>>> a < x < b:
```

This clearly shows that Guido Van Rossum, who invented the Python programming language, was a trained mathematician. Equally, the condition $a \leq x \leq b$ where the limits are included in the interval can be written using the same shorthand notation in Python.

```
>>> a <= x <= b:
```
